

During the day, we rest at the bottom of the sea, where the light does not reach so that the fish cannot see us. At night, we go up to the surface to eat algae. This is how we avoid being eaten by fish.

To learn more: Most copepod species migrate daily in a few hours, from the deep and dark areas of the ocean (between 100 and 1,000 meters deep), where they remain during the day away from predators, to the surface during the night (when they are invisible to visual predators), where they feed on phytoplankton and microzooplankton.
